Special discrete distributions From Poisson process to Poisson distribution

э

Special discrete distributions From Poisson process to Poisson distribution

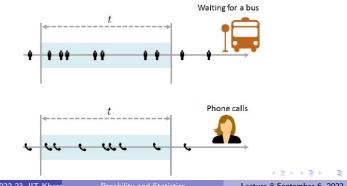

Poisson process (PP)

A Poisson Process is a model for a series of discrete events where the average time between events is known, but the exact timing of events is random. The arrival of an event is independent of the event before (waiting time between events is memoryless).

Special discrete distributions From Poisson process to Poisson distribution

Poisson process (PP)

A Poisson Process is a model for a series of discrete events where the average time between events is known, but the exact timing of events is random. The arrival of an event is independent of the event before (waiting time between events is memoryless).

Note The average time between events is known but they are randomly spaced (stochastic)

Criteria of PP

• Events are independent of each other. The occurrence of one event does not affect the probability another event will occur.

Note The average time between events is known but they are randomly spaced (stochastic)

Criteria of PP

- Events are independent of each other. The occurrence of one event does not affect the probability another event will occur.
- In the average rate (events per time period) is constant.

Note The average time between events is known but they are randomly spaced (stochastic)

Criteria of PP

- Events are independent of each other. The occurrence of one event does not affect the probability another event will occur.
- Interpretation of the second state of the s
- Two events cannot occur at the same time.

Note The average time between events is known but they are randomly spaced (stochastic)

Criteria of PP

- Events are independent of each other. The occurrence of one event does not affect the probability another event will occur.
- In the average rate (events per time period) is constant.
- Two events cannot occur at the same time.

Note Events are not simultaneous — means we can think of each sub-interval of a Poisson process as a Bernoulli Trial, that is, either a success or a failure. (Bus arrivals need not perfectly follow all the criteria)

Poisson Distribution probability mass function gives the probability of observing k events in a time period given the length of the period and the average events per time:

 $P(k \text{ events in time period}) = e^{-\frac{\text{events}}{\text{time}} \times \text{time period}} \frac{\left(\frac{\text{events}}{\text{time}} \times \text{time period}\right)^k}{k!}$

Poisson Distribution probability mass function gives the probability of observing k events in a time period given the length of the period and the average events per time:

 $P(k \text{ events in time period}) = e^{-\frac{\text{events}}{\text{time}} \times \text{time period}} \frac{\left(\frac{\text{events}}{\text{time}} \times \text{time period}\right)^k}{k!}$

Setting

$$\lambda = \frac{\text{events}}{\text{time}} \times \text{time period}$$

- = expected number of events in the time interval (time period)
- = rate parameter

we obtain the desired pmf.

Click the link: The Waiting Time Paradox, or, Why Is My Bus Always Late?

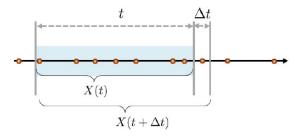

How is the formula obtained?

How is the formula obtained? Let X(t) denote the number of events in an integration time t. Then P(X(t) = k) denotes the probability of observing k events.

3

(B)

How is the formula obtained? Let X(t) denote the number of events in an integration time t. Then P(X(t) = k) denotes the probability of observing k events.

For small $\triangle t$,

$$P(X(t + riangle t) - X(t) = 1) = \lambda \cdot riangle t$$

where λ is the rate of occurance of events. Here $X(t + \triangle) - X(t)$ can be thought as a Bernoulli trial.

Thus, $P(X(t + \triangle t) - X(t) = 0) = 1 - \lambda \cdot \triangle t$.

3

(日) (四) (日) (日) (日)

Thus,
$$P(X(t + \triangle t) - X(t) = 0) = 1 - \lambda \cdot \triangle t$$
.
Then

$$P(X(t + \triangle t) = k)$$

$$= P[X(t) = k] \cdot (1 - \lambda \triangle t) + P[X(t) = k - 1] \cdot (\lambda \triangle t)$$

$$= P[X(t) = k] - P[X(t) = k]\lambda \triangle t + P[X(t) = k - 1]\lambda \triangle t.$$

Thus,
$$P(X(t + \triangle t) - X(t) = 0) = 1 - \lambda \cdot \triangle t$$
.
Then

$$P(X(t + \triangle t) = k)$$

= $P[X(t) = k] \cdot (1 - \lambda \triangle t) + P[X(t) = k - 1] \cdot (\lambda \triangle t)$
= $P[X(t) = k] - P[X(t) = k]\lambda \triangle t + P[X(t) = k - 1]\lambda \triangle t.$

Thus

$$\frac{P[X(t+\triangle t)=k]-P[X(t)=k]}{\triangle t}=\lambda\left(P[X(t)=k-1]-P[X(t)=k]\right).$$

< 行

Thus,
$$P(X(t + \triangle t) - X(t) = 0) = 1 - \lambda \cdot \triangle t$$
.
Then

$$P(X(t + \triangle t) = k)$$

= $P[X(t) = k] \cdot (1 - \lambda \triangle t) + P[X(t) = k - 1] \cdot (\lambda \triangle t)$
= $P[X(t) = k] - P[X(t) = k]\lambda \triangle t + P[X(t) = k - 1]\lambda \triangle t.$

Thus

$$\frac{P[X(t+\bigtriangleup t)=k]-P[X(t)=k]}{\bigtriangleup t}=\lambda\left(P[X(t)=k-1]-P[X(t)=k]\right).$$

Setting $\triangle t \rightarrow 0$ we obtain the ODE

$$\frac{d}{dt}P[X(t)=k] = \lambda \left(P[X(t)=k-1] - P[X(t)=k]\right)$$

Claim: $P(X(t) = k) = \frac{(\lambda t)^k}{k!}e^{-\lambda t}$ is the solution of the ODE.

イロト 不得下 イヨト イヨト 二日

Claim: $P(X(t) = k) = \frac{(\lambda t)^k}{k!}e^{-\lambda t}$ is the solution of the ODE.

$$\frac{d}{dt}\left(\frac{(\lambda t)^{k}}{k!}e^{-\lambda t}\right) = \lambda \frac{(\lambda t)^{k-1}}{(k-1)!}e^{-\lambda t} - \lambda \frac{(\lambda t)^{k}}{k!}e^{-\lambda t}$$
$$= \lambda (P[X(t) = k-1] - P[X(t) = k])$$

イロト 不得下 イヨト イヨト 二日

Claim: $P(X(t) = k) = \frac{(\lambda t)^k}{k!}e^{-\lambda t}$ is the solution of the ODE.

$$\frac{d}{dt}\left(\frac{(\lambda t)^{k}}{k!}e^{-\lambda t}\right) = \lambda \frac{(\lambda t)^{k-1}}{(k-1)!}e^{-\lambda t} - \lambda \frac{(\lambda t)^{k}}{k!}e^{-\lambda t}$$
$$= \lambda (P[X(t) = k-1] - P[X(t) = k])$$

Setting t = 1 we obtain the Poisson distribution
