

Informed State Space Search

Course: CS40002

Instructor: Dr. Pallab Dasgupta

Department of Computer Science & Engineering
Indian Institute of Technology Kharagpur

The notion of heuristics

- Heuristics use domain specific knowledge to estimate the quality or potential of partial solutions
- Examples:
 - ◆ Manhattan distance heuristic for 8 puzzle
 - ◆ Minimum Spanning Tree heuristic for TSP
 - ◆ Heuristics are fundamental to chess programs

The informed search problem

- **Given:** $[S, s, O, G, h]$ where
 - S is the (implicitly specified) set of states
 - s is the start state
 - O is the set of state transition operators each having some cost
 - G is the set of goal states
 - $h()$ is a heuristic function estimating the distance to a goal
- **To find:**
 - A min cost seq. of transitions to a goal state

Algorithm A*

- 1. Initialize:** Set $OPEN = \{s\}$, $CLOSED = \{ \}$,
 $g(s) = 0$, $f(s) = h(s)$
- 2. Fail:** If $OPEN = \{ \}$, Terminate & fail
- 3. Select:** Select the minimum cost state, n ,
from $OPEN$. Save n in $CLOSED$
- 4. Terminate:** If $n \in G$, terminate with success,
and return $f(n)$

Algorithm A*

5. Expand: For each successor, m , of n

If $m \notin [\text{OPEN} \cup \text{CLOSED}]$

Set $g(m) = g(n) + C(n,m)$

Set $f(m) = g(m) + h(m)$

Insert m in OPEN

If $m \in [\text{OPEN} \cup \text{CLOSED}]$

Set $g(m) = \min \{ g(m), g(n) + C(n,m) \}$

Set $f(m) = g(m) + h(m)$

If $f(m)$ has decreased and $m \in \text{CLOSED}$,
move m to OPEN

6. Loop: Go To Step 2.

Results on A*

A heuristic is called admissible if it always under-estimates, that is, we always have $h(n) \leq f^*(n)$, where $f^*(n)$ denotes the minimum distance to a goal state from state n

- For finite state spaces, A* always terminates

Results on A*

- At any time time before A* terminates, there exists in OPEN a state n that is on an optimal path from s to a goal state, with $f(n) \leq f^*(s)$
- If there is a path from s to a goal state, A* terminates (even when the state space is infinite)

Results on A^*

- Algorithm A^* is admissible, that is, if there is a path from s to a goal state, A^* terminates by finding an optimal path
- If A_1 and A_2 are two versions of A^* such that A_2 is more informed than A_1 , then A_1 expands at least as many states as does A_2 .
 - ◆ If we are given two or more admissible heuristics, we can take their max to get a stronger admissible heuristic.

Monotone Heuristics

- An admissible heuristic function, $h()$, is monotonic if for every successor m of n :

$$h(n) - h(m) \leq c(n,m)$$

- If the monotone restriction is satisfied, then A^* has already found an optimal path to the state it selects for expansion.
- If the monotone restriction is satisfied, the f -values of the states expanded by A^* is non-decreasing.

Pathmax

- **Converts a non-monotonic heuristic to a monotonic one:**
 - ◆ **During generation of the successor, m of n we set:**
$$h'(m) = \max \{ h(m), h(n) - c(n,m) \}$$
and use $h'(m)$ as the heuristic at m .

Inadmissible heuristics

- Advantages:

- ◆ In many cases, inadmissible heuristics can cause better pruning and significantly reduce the search time

- Drawbacks:

- ◆ A* may terminate with a sub-optimal solution

Iterative Deepening A* (IDA*)

1. Set $C = f(s)$

2. Perform DFBB with cut-off C

Expand a state, n , only if its f -value is less than or equal to C

If a goal is selected for expansion then return C and terminate

3. Update C to the minimum f -value which exceeded C among states which were examined and Go To Step 2.

Iterative Deepening A*: *bounds*

- In the worst case, only one new state is expanded in each iteration
 - ◆ If A* expands N states, then IDA* can expand:

$$1 + 2 + 3 + \dots + N = O(N^2)$$

- IDA* is asymptotically optimal

Memory bounded A*: MA*

- ◆ Whenever $|\text{OPEN} \cup \text{CLOSED}|$ approaches M , some of the least promising states are removed
- ◆ To guarantee that the algorithm terminates, we need to back up the cost of the most promising leaf of the subtree being deleted at the root of that subtree
- ◆ Many variants of this algorithm have been studied. Recursive Best-First Search (RBFS) is a linear space version of this algorithm

Multi-Objective A*: MOA*

- **Adaptation of A* for solving multi-criteria optimization problems**
 - ◆ Traditional approaches combine the objectives into a single one
 - ◆ In multi-objective state space search, the dimensions are retained
- **Main concepts:**
 - ◆ Vector valued state space
 - ◆ Vector valued cost and heuristic functions
 - ◆ Non-dominated solutions

Iterative Refinement Search

- We iteratively try to improve the solution
 - ◆ Consider all states laid out on the surface of a landscape
 - ◆ The notion of local and global optima
- Two main approaches
 - ◆ Hill climbing / Gradient descent
 - ◆ Simulated annealing

Hill Climbing / Gradient Descent

- ◆ **Makes moves which monotonically improve the quality of solution**
- ◆ **Can settle in a local optima**
- ◆ **Random-restart hill climbing**

Simulated Annealing

- Let T denote the temperature. Initially T is high. During iterative refinement, T is gradually reduced to zero.
1. Initialize T
 2. If $T=0$ return current state
 3. Set next = a randomly selected succ of current
 4. $\Delta E = \text{Val}[\text{next}] - \text{Val}[\text{current}]$
 5. If $\Delta E > 0$ then Set current = next
 6. Otherwise Set current = next with prob $e^{\Delta E/T}$
 7. Update T as per schedule and Go To Step 2.
